Your code has several syntax and logical errors. Let's walk through the issues one by one and then I'll provide a corrected version of your code:

Issues:

1. Function Definitions:

- You have syntax errors in the function definitions, such as missing colons (:) after function signatures.

2. Incorrect Syntax in `print`:

- In the `print` function, you're not properly closing strings with quotation marks.
- There are some undefined or misplaced variables and strings in the print statements.

3. Variable Name Mistakes:

- The variable `user0ption` should be `userOption` (you have 0 in the variable name).
- In function calls and prints, you refer to variables like `userFirstNumber` and `userSecondNumber`, but they haven't been defined in your code.
- `sum`, `difference`, `product`, `quotient` are integers, so you need to handle them correctly when printing. You cannot directly concatenate an integer to a string unless you convert it to a string.

4. Spelling Errors in Function Names:

- `muliiplyNumbers` should be `multiplyNumbers`.
- `deviedNumbers` should be `divideNumbers`.
- `displaymenu` should be `displayMenu`.

5. Function Parameters:

- `displayMenu` takes no parameters, but you incorrectly pass "Welcome to my calculator" to it.
- In `addNumbers`, `subtractNumbers`, `multiplyNumbers`, and `divideNumbers`, you're missing the correct syntax for parameters, and you aren't passing the correct values (like `userFirstNumber` and `userSecondNumber`).

Corrected Code:

python

Copy code

```
def theSecondProject():
```

```
print("Heyyyy you guys")
print("Manvi")
print("Manvi")

# Call the function
theSecondProject()
theSecondProject()

# Function to display the menu
def displayMenu():
    print("Welcome to my calculator!")
    print("1. Addition")
    print("2. Subtraction")
    print("3. Multiplication")
    print("4. Division")

# Function to add two numbers
def addNumbers(firstNumber, secondNumber):
    sum = firstNumber + secondNumber
    print(f"The sum of {firstNumber} and {secondNumber} is {sum}")

# Function to subtract two numbers
def subtractNumbers(firstNumber, secondNumber):
    difference = firstNumber - secondNumber
    print(f"The difference of {firstNumber} and {secondNumber} is {difference}")

# Function to multiply two numbers
def multiplyNumbers(firstNumber, secondNumber):
    product = firstNumber * secondNumber
    print(f"The product of {firstNumber} and {secondNumber} is {product}")

# Function to divide two numbers
def divideNumbers(firstNumber, secondNumber):
    if secondNumber != 0:
        quotient = firstNumber / secondNumber
```

```

        print(f"The quotient of {firstNumber} and {secondNumber} is
{quotient}")
    else:
        print("Error: Cannot divide by zero.")

# Main function
def main():
    # Display the menu
    displayMenu()

    # Get user input for the operation
    userOption = int(input("Please select an option: "))

    # Get user input for numbers
    userFirstNumber = float(input("Enter the first number: "))
    userSecondNumber = float(input("Enter the second number: "))

    # Execute based on user option
    if userOption == 1:
        addNumbers(userFirstNumber, userSecondNumber)
    elif userOption == 2:
        subtractNumbers(userFirstNumber, userSecondNumber)
    elif userOption == 3:
        multiplyNumbers(userFirstNumber, userSecondNumber)
    elif userOption == 4:
        divideNumbers(userFirstNumber, userSecondNumber)
    else:
        print("Invalid option selected.")

# Call the main function to start the program
main()

```

Explanation of Fixes:

1. **Function Definitions:** All function definitions now have proper colons at the end (`def functionName():`).
2. **Print Statements:** Fixed print statements with string formatting (`f"..."`) so you can correctly display variables.

3. **Variable Handling:** Ensured the user input is correctly handled with `input()` and converted to `float` for calculations.
4. **Menu Display:** The `displayMenu()` function no longer takes unnecessary parameters.
5. **Error Handling:** Added a check to prevent division by zero in the `divideNumbers()` function.

Now your code should run as expected and display a simple calculator menu that lets the user select an operation and perform calculations.
